Cardiac resynchronization therapy for patients with heart failure and reduced ejection fraction. Cardiac resynchronization therapy (CRT) provides a benefit of 6.5% in the improvement of 6-minute walking test and 6.1% in the improvement of NYHA class in patients with heart failure and reduced ejection fraction. The risk of CRT was 1.4% death, 7.3% peri-procedural complications and 5.2% device implantation failure. There was no significant difference in hospitalization between CRT and non-CRT group. In patients with left ventricular (LV) resynchronization, QRS prolongation >180 ms was not a determinant of response to CRT. LV reverse remodeling is a strong predictor of response
